ExploitingCond.Ind.(Recap)

- Let'sseewhatconditionalindependencebuysus
- Considerastory:
 - IfCraigwokeuptooearlyE,Craigprobablyneeds coffeeC;ifC,Craigneedscoffee,he'slikelyangryA. IfA,thereisanincreasedchanceofananeurysm (burstbloodvessel)B.lfB,Craigisquitelikelytobe hospitalizedH.

E - Craig woke too early A - Craig is angry H - Craig hospitalized C - Craig needs coffee B - Craig burst a blood vessel

Cond'l Ind.inourStory(Recap)

- ■IfyoulearnedanyofE,C,A,orB,yourassessmentof Pr(H)wouldchange.
 - E.g., if any of these are seen to be true, you would increasePr(h)anddecreasePr(~h).
 - SoHis notindependent ofE,orC,orA,orB.
- ■ButifyouknewvalueofB(trueorfalse),learningvalue ofE.C.orA.wouldnotinfluencePr(H).Influencethese factors have on His mediated by their influence on B.
 - Craigdoesn'tgetsenttothehospitalbecausehe'sangry,he getssentbecausehe'shadananeurysm.
 - SoHis independent of E, and C, and A,

Cond'l Ind.inourStory(Recap)

given B

- ■SoHis independent of E, and C, and A,
- Similarly:
- Bis independent of E, and C, given A
- Ais independent of E, given C
- ■Thismeansthat:
 - Pr(H |B,{A,C,E})=Pr(H|B)
 - ■i.e.,foranysubsetof{A,C,E},thisrelationholds
 - Pr(B |A,{C,E})=Pr(B |A)
 - Pr(A |C,{E})=Pr(A |C)
 - Pr(C |E)andPr(E)don't"simplify"

Cond'l Ind.inourStory(Recap)

- ■Bythechainrule(foranyinstantiationofH...E):
 - Pr(H,B,A,C,E)=

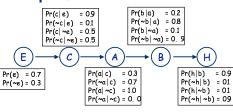

Pr(H|B,A,C,E)Pr(B|A,C,E)Pr(A|C,E)Pr(C|E)Pr(E)

- Byourindependenceassumptions:
 - Pr(H,B,A,C,E)=

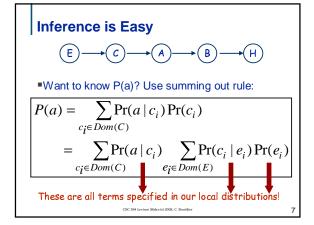

Pr(H|B)Pr(B|A)Pr(A|C)Pr(C|E)Pr(E)

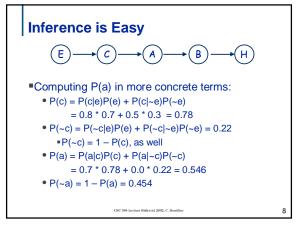

Wecanspecifythefulljointbyspecifyingfive localconditionaldistributions: Pr(H|B); Pr(B|A); Pr(A|C);Pr(C|E);andPr(E)

ExampleQuantification

- Specifyingthejointrequiresonly9parameters(if wenotethathalfoftheseare"1minus"the others), instead of 31 for explicit representation
 - linearinnumberofvars insteadofexponential!
 - lineargenerallyifdependencehasachainstructure

Bayesian Networks

- ■The structure above is a *Bayesian network*. A BN is a *graphical representation* of the direct dependencies over a set of variables, together with a set of *conditional probability tables (CPTs)* quantifying the strength of those influences.
- Bayes nets generalize the above ideas in very interesting ways, leading to effective means of representation and inference under uncertainty.

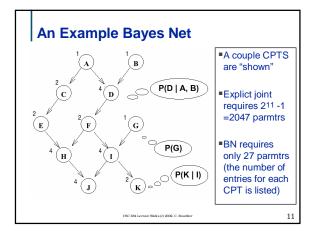

CSC 384 Lecture Slides (c) 2002, C. Boutilie

Bayesian Networks

- ■A BN over variables $\{X_1, X_2, ..., X_n\}$ consists of:
 - a DAG whose nodes are the variables
 - a set of CPTs $Pr(X_i | Par(X_i))$ for each X_i
- •Key notions (see text for defn's, all are intuitive):
 - parents of a node: Par(Xi)
 - children of node
 - descendents of a node
 - ancestors of a node
 - family: set of nodes consisting of X_i and its parents
 CPTs are defined over families in the BN

CSC 384 Lecture Slides (c) 2002, C. Boutilier

10

Semantics of a Bayes Net

■The structure of the BN means: every *X_i* is conditionally independent of all of its nondescendants given it parents:

 $Pr(X_i | S \cup Par(X_i)) = Pr(X_i | Par(X_i))$

for any subset $S \subseteq NonDescendents(X_i)$

CSC 384 Lecture Slides (c) 2002, C. Boutilier

12

Semantics of Bayes Nets (2)

- If we ask for Pr(x₁, x₂,..., x_n) we obtain
 assuming an ordering consistent with network
- ■By the chain rule, we have:

 $Pr(x_1, x_2,..., x_n) = Pr(x_n \mid x_{n-1}, ..., x_1) Pr(x_{n-1} \mid x_{n-2},..., x_1) ... Pr(x_1)$ $= Pr(x_n \mid Par(x_{n-1})) Pr(x_{n-1} \mid Par(x_{n-2})) ... Pr(x_1)$

Thus, the joint is recoverable using the parameters (CPTs) specified in an arbitrary BN

CSC 384 Lecture Slides (c) 2002, C. Boutilier

Constructing a Bayes Net

•Given any distribution over variables $X_1, X_2,..., X_n$, we can construct a Bayes net that faithfully represents that distribution.

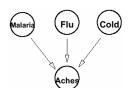

Take any ordering of the variables (say, the order given), and go through the following procedure for X_n down to X_1 . Let $\operatorname{Par}(X_n)$ be any subset $S \subseteq \{X_1, \dots, X_{n-1}\}$ such that X_n is independent of $\{X_1, \dots, X_{n-1}\}$ - S given S. Such a subset must exist (convince yourself). Then determine the parents of X_{n-1} the same way, finding a similar $S \subseteq \{X_1, \dots, X_{n-2}\}$, and so on. In the end, a DAG is produced and the BN semantics must hold by construction.

CSC 384 Lecture Slides (c) 2002, C. Boutilie

4.4

Causal Intuitions

- ■The construction of a BN is simple
 - works with arbitrary orderings of variable set
 - but some orderings much better than others!
 - generally, if ordering/dependence structure reflects causal intuitions, a more natural, compact BN results

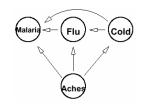

- ■In this BN, we've used the ordering Mal, Cold, Flu, Aches to build BN for distribution P
 - Variable can only have parents that come earlier in the ordering

Lecture Slides (c) 2002, C. Boutilier

Causal Intuitions

- ■Suppose we build the BN for distribution P using the opposite ordering
 - i.e., we use ordering Aches, Cold, Flu, Malaria
 - resulting network is more complicated!

- •Mal depends on Aches; but it also depends on Cold, Flu given Aches
 - Cold, Flu explain away Mal given Aches
- •Flu depends on Aches; but also on Cold *given* Aches
- Cold depends on Aches

CSC 384 Lecture Slides (c) 2002, C. Boutilier

1

Testing Independence

- •Given BN, how do we determine if two variables X, Y are independent (given evidence E)?
 - we use a (simple) graphical property
- ■D-separation: A set of variables E d-separates X and Y if it blocks every undirected path in the BN between X and Y. (We'll define blocks next.)
- X and Y are conditionally independent given evidence E if E d-separates X and Y
 - thus BN gives us an easy way to tell if two variables are independent (set E = Ø) or cond. independent

CSC 384 Lecture Slides (c) 2002, C. Boutilier

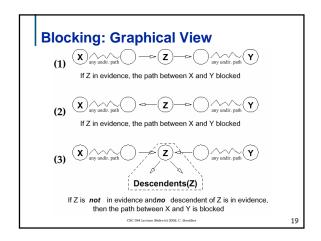

17

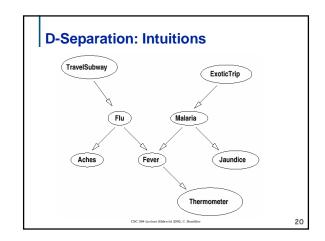

Blocking in D-Separation

- Let P be an undirected path from X to Y in a BN. Let E be an evidence set. We say E blocks path P iff there is some node Z on the path such that:
 - Case 1: one arc on P *goes into* Z and one *goes out* of Z, and Z∈E; or
 - Case 2: both arcs on P leave Z, and Z∈E; or
 - Case 3: both arcs on P enter Z and neither Z, nor any of its descendents, are in E.

CSC 384 Lecture Slides (c) 2002, C. Boutilier

18

D-Separation: Intuitions

- Subway and Therm are dependent; but are independent given Flu (since Flu blocks the only path)
- Aches and Fever are dependent; but are independent given Flu (since Flu blocks the only path). Similarly for Aches and Therm (dependent, but indep. given Flu).
- ■Flu and Mal are indep. (given no evidence): Fever blocks the path, since it is not in evidence, nor is its decsendant Therm. Flu, Mal are dependent given Fever (or given Therm): nothing blocks path now.
- Subway, Exotic Trip are indep.; they are dependent given Therm; they are indep. given Therm and Malaria. This for exactly the same reasons for Flu/Mal above.

23

Inference in Bayes Nets

- ■The independence sanctioned by D-separation allows us to compute prior and posterior probabilities quite effectively.
- ■We'll look at a couple simple examples to illustrate. We'll focus on networks without loops. (A loop is a cycle in the underlying *undirected* graph. Recall the directed graph has no cycles.)

24

Simple Forward Inference (Chain)

■Computing prior require simple forward "propagation" of probabilities (using Subway net)

 $P(J) = \sum_{M,ET} P(J|M,ET) P(M,ET)$

 $= \Sigma_{M,ET} P(J|M) P(M|ET) P(ET)$ $= \Sigma_{M} P(J|M) \Sigma_{ET} P(M|ET) P(ET)$

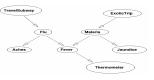

■(1) follows by summing out rule; (2) by chain rule and independence; (3) by distribution of sum

- Note: all (final) terms are CPTs in the BN
- · Note: only ancestors of J considered

Simple Forward Inference (Chain)

Same idea applies when we have "upstream" evidence

 $P(J \mid et) = \Sigma_M P(J \mid M,et) P(M \mid et)$ $= \Sigma_M P(J \mid M) P(M \mid et)$

Simple Forward Inference (Pooling)

■Same idea applies with multiple parents

 $P(Fev) = \Sigma_{Flu,M} P(Fev|Flu,M) P(Flu,M)$

- = $\Sigma_{\text{Flu} M} P(\text{Fev}|\text{Flu},M) P(\text{Flu}) P(M)$
- = $\Sigma_{\text{Flu},\text{M}}$ P(Fev|Flu,M) Σ_{TS} P(Flu|TS) P(TS) Σ_{FT} P(M|ET) P(ET)
- ■(1) follows by summing out rule; (2) by independence of Flu, M; (3) by summing out
 - note: all terms are CPTs in the Bayes net

CSC 384 Lecture Slides (c) 2002, C. Boutilier

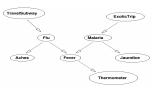

25

Simple Forward Inference (Pooling)

Same idea applies with evidence

 $P(Fev|ts,\sim m) = \sum_{Flu} P(Fev|Flu,ts,\sim m) P(Flu|ts,\sim m)$

=
$$\Sigma_{Flu}$$
 P(Fev|Flu,~m) P(Flu|ts)

26

Simple Backward Inference

■When evidence is downstream of query variable, we must reason "backwards." This requires the use of Bayes rule:

 $P(ET | j) = \alpha P(j | ET) P(ET)$

- = $\alpha \Sigma_M P(j \mid M,ET) P(M|ET) P(ET)$
- = $\alpha \Sigma_M P(j \mid M) P(M|ET) P(ET)$
- ■First step is just Bayes rule
 - normalizing constant α is 1/P(j); but we needn't compute it explicitly if we compute P(ET | j) for each value of ET: we just add up terms P(j | ET) P(ET) for all values of ET (they sum to P(j))

Backward Inference (Pooling)

Same ideas when several pieces of evidence lie "downstream"

 $P(ET | j,fev) = \alpha P(j,fev | ET) P(ET)$

- = $\alpha \Sigma_{M} P(j,fev \mid M,ET) P(M|ET) P(ET)$
- = $\alpha \Sigma_{M} P(j, \text{fev} \mid M) P(M|ET) P(ET)$
- = $\alpha \Sigma_M P(j \mid M) P(fev \mid M) P(M|ET) P(ET)$
- Same steps as before; but now we compute prob of both pieces of evidence given hypothesis ET and combine them. Note: they are independent given M; but not given ET.
- Still must simplify P(fev|M) down to CPTs (as usual)

Variable Elimination

- The intuitions in the above examples give us a simple inference algorithm for networks without loops: the polytree algorithm. We won't discuss it further. But be comfortable with the intuitions.
- Instead we'll look at a more general algorithm that works for general BNs; but the propagation algorithm will more or less be a special case.
- ■The algorithm, *variable elimination*, simply applies the summing out rule repeatedly. But to keep computation simple, it exploits the independence in the network and the ability to distribute sums inward.
